Mathematics (2)

2.1 Equations

The extremum of a quadtratic is given by $x = -b/2a$.
Cramer: Given an equation $Ax = b$, the solution to a variable x_i is given by $x_i = \frac{\det A'_i}{\det A}$ [where A'_i is A with the i 'th column replaced by b .]

Vieta: Let $P(x) = a_n x^n + \dots + a_0$, be a polynomial with complex coefficients and degree n , having complex roots $r_n, \dots, r_1$. Then for any integer $0 \leq k \leq n$,

$$\sum_{1 \leq i_1 < i_2 < \dots < i_k \leq n} r_{i_1} r_{i_2} \dots r_{i_k} = (-1)^k \frac{a_{n-k}}{a_n}$$

Rational Root Theorem: If $\frac{p}{q}$ is a reduced rational root of a polynomial with integer coeffs, then $p \mid a_0$ and $q \mid a_n$

2.2 Ceils and Floors

For $x, y \in \mathbb{R}$, $m, n \in \mathbb{Z}$:

- $\lfloor x \rfloor \leq x < \lfloor x \rfloor + 1$; $\lceil x \rceil - 1 < x \leq \lceil x \rceil$
- $-\lfloor x \rfloor = \lceil -x \rceil$; $-\lceil x \rceil = \lfloor -x \rfloor$
- $\lfloor x + n \rfloor = \lfloor x \rfloor + n$, $\lceil x + n \rceil = \lceil x \rceil + n$
- $\lfloor x \rfloor = m \Leftrightarrow x - 1 < m \leq x < m + 1$
- $\lceil x \rceil = n \Leftrightarrow n - 1 < x \leq n < x + 1$
- If $n > 0$, $\lfloor \frac{\lfloor x \rfloor + m}{n} \rfloor = \lfloor \frac{x + m}{n} \rfloor$
- If $n > 0$, $\lceil \frac{\lceil x \rceil + m}{n} \rceil = \lceil \frac{x + m}{n} \rceil$
- If $n > 0$, $\lfloor \frac{\lfloor \frac{x}{m} \rfloor}{n} \rfloor = \lfloor \frac{x}{mn} \rfloor$
- If $n > 0$, $\lceil \frac{\lceil \frac{x}{m} \rceil}{n} \rceil = \lceil \frac{x}{mn} \rceil$
- For $m, n > 0$, $\sum_{k=1}^{n-1} \lfloor \frac{km}{n} \rfloor = \frac{(m-1)(n-1) + \gcd(m,n) - 1}{2}$

2.3 Recurrences

If $a_n = c_1 a_{n-1} + \dots + c_k a_{n-k}$, and $r_1, \dots, r_k$ are distinct roots of $x^k - c_1 x^{k-1} - \dots - c_k$, there are $d_1, \dots, d_k$ s.t.

$$a_n = d_1 r_1^n + \dots + d_k r_k^n.$$

Non-distinct roots r become polynomial factors, e.g. $a_n = (d_1 n + d_2) r^n$.

2.4 Trigonometry

$$\begin{aligned} \sin(v+w) &= \sin v \cos w + \cos v \sin w \\ \cos(v+w) &= \cos v \cos w - \sin v \sin w \\ \tan(v+w) &= \frac{\tan v + \tan w}{1 - \tan v \tan w} \\ \sin v + \sin w &= 2 \sin \frac{v+w}{2} \cos \frac{v-w}{2} \\ \cos v + \cos w &= 2 \cos \frac{v+w}{2} \cos \frac{v-w}{2} \end{aligned}$$

$(V+W) \tan(\frac{v-w}{2}) = (V-W) \tan(\frac{v+w}{2})$
 V, W are sides opposite to angles v, w .
 $a \cos x + b \sin x = r \cos(x - \phi)$
 $a \sin x + b \cos x = r \sin(x + \phi)$
where $r = \sqrt{a^2 + b^2}$, $\phi = \text{atan2}(b, a)$.

2.5 Geometry

2.5.1 Triangles

Side lengths: a, b, c

Semiperimeter: $p = \frac{a + b + c}{2}$

Area: $A = \sqrt{p(p - a)(p - b)(p - c)}$

Circumradius: $R = \frac{abc}{4A}$

Inradius: $r = \frac{A}{p}$

Length of median (divides triangle into two equal-area triangles):

$m_a = \frac{1}{2}\sqrt{2b^2 + 2c^2 - a^2}$

Length of bisector (divides angles in two):

$s_a = \sqrt{bc[1 - (a/(b + c))^2]}$

Law of sines, cosines & tangents:

$\frac{\sin \alpha}{a} = \frac{\sin \beta}{b} = \frac{\sin \gamma}{c} = \frac{1}{2R}.....(1)$

$a^2 = b^2 + c^2 - 2bc \cos \alpha.....(2)$

2.5.2 Quadrilaterals

With side lengths a, b, c, d ; diagonals e, f , diagonals angle θ , area A and magic flux $F = b^2 + d^2 - a^2 - c^2$:

$4A = 2ef \cdot \sin \theta = F \tan \theta = \sqrt{4e^2f^2 - F^2}$

For cyclic quadrilaterals the sum of opposite angles is π . **Spherical coordinates**

$A = \sqrt{(p - a)(p - b)(p - c)(p - d)}$

$$\begin{aligned} x &= r \sin \theta \cos \phi & r &= \sqrt{x^2 + y^2 + z^2} \\ y &= r \sin \theta \sin \phi & \theta &= \operatorname{acos}(z/\sqrt{x^2 + y^2 + z^2}) \\ z &= r \cos \theta & \phi &= \operatorname{atan2}(y, x) \end{aligned}$$

2.6 Derivatives/Integrals

$\frac{d}{dx} \arcsin x = \frac{1}{\sqrt{1 - x^2}} \quad \frac{d}{dx} \arccos x = -\frac{1}{\sqrt{1 - x^2}}$

$\frac{d}{dx} \tan x = 1 + \tan^2 x \quad \frac{d}{dx} \arctan x = \frac{1}{1 + x^2}$

$\int \tan ax = -\frac{\ln |\cos ax|}{a} \quad \int xe^{ax} dx = \frac{e^{ax}}{a^2}(ax - 1)$

$\int e^{-x^2} = \frac{\sqrt{\pi}}{2} \operatorname{erf}(x) \quad \int x \sin ax = \frac{\sin ax - ax \cos ax}{a^2}$

$\int_a^b f(x)g(x)dx = [F(x)g(x)]_a^b - \int_a^b F(x)g'(x)dx$

2.7 Sums

$c^a + c^{a+1} + \dots + c^b = \frac{c^{b+1} - c^a}{c - 1}, c \neq 1$

$1^4 + 2^4 + 3^4 + \dots + n^4 = S_2 \times \frac{3n^2 + 3n - 1}{5} = S_4$

$b \sum_{k=0}^{n-1} (a + kd)r^k = \frac{ab - (a + nd)br^n}{1 - r} + \frac{dbr(1 - r^n)}{(1 - r)^2}$

To compute $1^k + \dots + n^k$ in $\mathcal{O}(k \lg k + k \lg MOD)$ compute first $t = k + 2$ sums $y_1, \dots, y_t$, then interpolate. Let $P = \prod_{i=1}^t (n - i)$. Then answer for n is

$$\sum_{i=1}^t \frac{P}{n - i} \cdot \frac{(-1)^{t-i} y_i}{(i - 1)!(t - i)!}$$

Also $S_k = \frac{1}{k+1} \sum_{j=0}^k (-1)^j \binom{k+1}{j} B_j n^{k+1-j}$ where B_i are Bernoulli numbers.

2.8 Series

$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots, (-\infty < x < \infty)$

$\ln(1 + x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots, (-1 < x \leq 1)$

$\sqrt{1 + x} = 1 + \frac{x}{2} - \frac{x^2}{8} + \frac{2x^3}{32} - \frac{5x^4}{128} + \dots, (-1 \leq x \leq 1)$

$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots, (-\infty < x < \infty)$

$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots, (-\infty < x < \infty)$

$(1 - x)^{-r} = \sum_{i=0}^{\infty} \binom{r + i - 1}{i} x^i, (r \in \mathbb{R})$

2.9 Bitwise Formulas

$$\begin{aligned} a|b &= a \oplus b + a \& b \\ a \oplus (a \& b) &= (a|b) \oplus b & a \oplus b &= (a \& b) \oplus (a|b) \\ a + b &= a|b + a \& b & a + b &= a \oplus b + 2(a \& b) \end{aligned}$$

$$\begin{aligned} a - b &= (a \oplus (a \& b)) - ((a|b) \oplus a) = \\ &((a|b) \oplus b) - ((a|b) \oplus a) = (a \oplus (a \& b)) - (b \oplus (a \& b)) = \\ &((a|b) \oplus b) - (b \oplus (a \& b)) \end{aligned}$$

2.10 Probability theory

Let X be a discrete random variable with probability $p_X(x)$ of assuming the value x . It will then have an expected value (mean) $\mu = \mathbb{E}(X) = \sum_x xp_X(x)$ and variance $\sigma^2 = V(X) = \mathbb{E}(X^2) - (\mathbb{E}(X))^2 = \sum_x (x - \mathbb{E}(X))^2 p_X(x)$ where σ is the standard deviation. If X is instead continuous it will have a probability density function $f_X(x)$ and the sums above will instead be integrals with $p_X(x)$ replaced by $f_X(x)$.

Expectation is linear:

$\mathbb{E}(aX + bY) = a\mathbb{E}(X) + b\mathbb{E}(Y)$

For independent X and Y ,

$V(aX + bY) = a^2V(X) + b^2V(Y).$

2.10.1 Discrete distributions

Binomial distribution

The number of successes in n independent yes/no experiments, each which yields success with probability p is

$\operatorname{Bin}(n, p)$, $n = 1, 2, \dots$, $0 \leq p \leq 1$.

$p(k) = \binom{n}{k} p^k (1 - p)^{n - k}$

$\mu = np, \sigma^2 = np(1 - p)$

$\operatorname{Bin}(n, p)$ is approximately $\operatorname{Po}(np)$ for small p .

First success distribution

The number of trials needed to get the first success in independent yes/no experiments, each which yields success with probability p is

$\operatorname{Fs}(p)$, $0 \leq p \leq 1$.

$p(k) = p(1 - p)^{k - 1}, k = 1, 2, \dots$

$\mu = \frac{1}{p}, \sigma^2 = \frac{1 - p}{p^2}$

Poisson distribution

The number of events occurring in a fixed period of time t if these events occur with a known average rate κ and independently of the time since the last event is $\operatorname{Po}(\lambda)$, $\lambda = t\kappa$.

$p(k) = e^{-\lambda} \frac{\lambda^k}{k!}, k = 0, 1, 2, \dots$

$\mu = \lambda, \sigma^2 = \lambda$

2.10.2 Continuous distributions

Uniform distribution

If the probability density function is constant between a and b and 0 elsewhere it is

$\operatorname{U}(a, b)$, $a < b$.

$$f(x) = \begin{cases} \frac{1}{b - a} & a < x < b \\ 0 & \text{otherwise} \end{cases}$$

$$\mu = \frac{a + b}{2}, \sigma^2 = \frac{(b - a)^2}{12}$$

Exponential distribution

The time between events in a Poisson process is $\operatorname{Exp}(\lambda)$, $\lambda > 0$.

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & x \geq 0 \\ 0 & x < 0 \end{cases}$$

$$\mu = \frac{1}{\lambda}, \sigma^2 = \frac{1}{\lambda^2}$$

Normal distribution

Most real random values with mean μ and variance σ^2 are well described by $\mathcal{N}(\mu, \sigma^2)$, $\sigma > 0$.

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x - \mu)^2}{2\sigma^2}}$$

If $X_1 \sim \mathcal{N}(\mu_1, \sigma_1^2)$ and $X_2 \sim \mathcal{N}(\mu_2, \sigma_2^2)$ then

$aX_1 + bX_2 + c \sim \mathcal{N}(\mu_1 + \mu_2 + c, a^2\sigma_1^2 + b^2\sigma_2^2)$

2.11 Markov chains

A *Markov chain* is a discrete random process with the property that the next state depends only on the current state. Let $X_1, X_2, \dots$ be a sequence of random variables generated by the Markov process. Then there is a transition matrix $\mathbf{P} = (p_{ij})$, with $p_{ij} = \Pr(X_n = i | X_{n-1} = j)$, and $\mathbf{p}^{(n)} = \mathbf{P}^n \mathbf{p}^{(0)}$ is the probability distribution for X_n (i.e., $p_i^{(n)} = \Pr(X_n = i)$), where $\mathbf{p}^{(0)}$ is the initial distribution.

π is a stationary distribution if $\pi = \pi \mathbf{P}$. If the Markov chain is *irreducible* (it is possible to get to any state from any state), then $\pi_i = \frac{1}{\mathbb{E}(T_i)}$ where $\mathbb{E}(T_i)$ is the expected time between two visits in state i . π_j / π_i is the expected number of visits in state j between two visits in state i .

For a connected, undirected and non-bipartite graph, where the transition probability is uniform among all neighbors, π_i is proportional to node i 's degree.

A Markov chain is *ergodic* if the asymptotic distribution is independent of the initial distribution. A finite Markov chain is ergodic iff it is irreducible and *aperiodic* (i.e., the gcd of cycle lengths is 1). $\lim_{k \rightarrow \infty} \mathbf{P}^k = \mathbf{1}\pi$.

A Markov chain is an $\mathbf{A}$ -chain if the states can be partitioned into two sets $\mathbf{A}$ and $\mathbf{G}$, such that all states in $\mathbf{A}$ are absorbing ($p_{ii} = 1$), and all states in $\mathbf{G}$ leads to an absorbing state in $\mathbf{A}$. The probability for absorption in state $i \in \mathbf{A}$, when the initial state is j , is $a_{ij} = p_{ij} + \sum_{k \in \mathbf{G}} a_{ik} p_{kj}$. The expected time until absorption, when the initial state is i , is $t_i = 1 + \sum_{k \in \mathbf{G}} p_{ki} t_k$.

2.12 Trivia

Pythagorean triples: The Pythagorean triples are uniquely generated by $a = k \cdot (m^2 - n^2)$, $b = k \cdot (2mn)$, $c = k \cdot (m^2 + n^2)$ with $m > n > 0$, $k > 0$, $\gcd(m,n) = 1$, both m,n not odd.
Primes: $p = 962592769$ is such that $2^{21} \mid p - 1$, which may be useful. For hashing use 970592641 (31-bit number), 31443539979727 (45-bit), 3006703054056749 (52-bit). There are 78498 primes less than 1 000 000.

Primitive roots modulo n exists iff $n = 1, 2, 4$ or, $n = p^k \cdot 2p^k$ where p is an odd prime. Furthermore, the number of roots are $\phi(\phi(n))$.

To Find Generator g of M , factor $M - 1$ and get the distinct primes p_i . If $g^{(M-1)/p_i} \neq 1(MODM)$ for each p_i then g is a valid root. Try all g until a hit is found (usually found very quick).

Esitmates: $\sum_{d|n} d = O(n \log \log n)$.

Prime count: 5133 upto 5e4. 9592 upto 1e5. 17984 upto 2e5. 78498 upto 1e6. 5761455 upto 1e8.

max NOD $\leq n$: 100 for $n = 5e4$. 500 for $n = 1e7$. 2000 for $n = 1e10$. 200 000 for $n = 1e19$.

max Unique Prime Factors: 6 upto 5e5. 7 upto 9e6. 8 upto 2e8. 9 upto 6e9. 11 upto 7e12. 15 upto 3e19.

Quadratic Residue: $(\frac{a}{p})$ is 0 if $p|a$, 1 if a is a quadratic residue, -1 otherwise. Euler: $(\frac{a}{p}) = a^{(p-1)/2}(\mod p)$ (prime). Jacobi: if $n = p_1^{e_1} \cdots p_k^{e_k}$ then $(\frac{a}{n}) = \prod (\frac{a}{p_i})^{e_i}$.

Chicken McNugget. If a,b coprime, there are $\frac{1}{2}(a-1)(b-1)$ numbers not of form $ax+by$ ($x,y \geq 0$), the largest being $ab-a-b$.

Data structures (3)

OrderStatisticTree.h

Description: A set (not multiset!) with support for finding the n'th element, and finding the index of an element. To get a map, change null_type.
Time: $O(\log N)$

```
#include <bits/extc++.h>
using namespace __gnu_pbds;

template<class T> using Tree=tree<T, null_type,
    tree_order_statistics_node_update>;

void example() {
    Tree<int> t, t2; t.insert(8);
    auto it = t.insert(10).first;
    assert(it == t.lower_bound(9));
    assert(t.order_of_key(10) == 1);
    assert(t.order_of_key(11) == 2);
    assert(*t.find_by_order(0) == 8);
    t.join(t2); // assuming T< T2 or T> T2,
                merge t2 into t
}
```

HashMap.h

Description: Hash map with mostly the same API as unordered_map, but ~3x faster. Uses 1.5x memory. Initial capacity must be a power of 2 (if provided).

```
#include <bits/extc++.h>
// To use most bits rather than just the
// lowest ones:
struct chash { // large odd number for C
    const uint64_t C = 11(4e18 * acos(0)) | 71;
    ll operator () (ll x) const { return
        __builtin_bswap64(x*C); }
};
__gnu_pbds::gp_hash_table<ll,int, chash> h({},{},{},{},{1<<16});
```

SegmentTreeKACTL.h

Description: Zero-indexed max-tree. Bounds are inclusive to the left and exclusive to the right. Can be changed by modifying T, f and unit.
Time: $O(\log N)$

```
struct Tree {
    typedef int T;
    static constexpr T unit = INT_MIN;
    T f(T a, T b) { return max(a, b); } // (any
        associative fn)
    vector<T> s; int n;
    Tree(int n = 0, T def = unit) : s(2*n, def),
        n(n) {}
    void update(int pos, T val) {
        for (s[pos += n] = val; pos /= 2;)
            s[pos] = f(s[pos * 2], s[pos * 2 + 1]);
    }
    T query(int b, int e) { // query [b, e)
        T ra = unit, rb = unit;
        for (b += n, e += n; b < e; b /= 2, e /=
            2) {
            if (b % 2) ra = f(ra, s[b++]);
            if (e % 2) rb = f(s[--e], rb);
        }
        return f(ra, rb);
    }
};
```

SegmentTree.h

Time: $O(\log N)$

```
template<class S> struct segtree {
    int n; V<S> t;
    void init(int _) { n = _; t.assign(n+n-1, S
        ()); }
    void vinit(const V<S>& v) {
        n = sz(v); t.assign(n + n - 1, S());
        build(0,0,n-1,v);
    } template<typename... T>
    void upd(int l, int r, const T&... v) {
        assert(0 <= l && l <= r && r < n);
        upd(0, 0, n-1, l, r, v...);
    }
    S get(int l, int r) {
        assert(0 <= l && l <= r && r < n);
        return get(0, 0, n-1, l, r);
    }
private:
    inline void push(int u, int b, int e) {
        if (t[u].lazy == 0) return;
        int mid = (b+e)>>1, rc = u+((mid-b+1)<<1);
        t[u+1].upd(b, mid, t[u].lazy);

```

PolyInterpolate.h

Description: Given n points $(x[i], y[i])$, computes an n -1-degree polynomial p that passes through them: $p(x) = a[0] * x^0 + \dots + a[n - 1] * x^{n-1}$. For numerical precision, pick $x[k] = c * \cos(k/(n - 1) * \pi), k = 0 \dots n - 1$. For fast interpolation in $\mathcal{O}(n \log^2 n)$ use Lagrange. $P(x) = \sum_{i=1}^n y_i \prod_{j \neq i} \frac{x-x_j}{x_i-x_j}$. To compute values $\prod_{j \neq i} (x_i - x_j)$ fast, compute $A(x) = \prod_{i=1}^n (x - x_i)$ with divide and conquer. The required values are $A'(x_i)$, (values at derivative), compute fast with multipoint evaluation.

Time: $\mathcal{O}(n^2)$

08bf48, 13 lines

```
typedef vector<double> vd;
vd interpolate(vd x, vd y, int n) {
    vd res(n), temp(n);
    rep(k,0,n-1) rep(i,k+1,n)
        y[i] = (y[i] - y[k]) / (x[i] - x[k]);
    double last = 0; temp[0] = 1;
    rep(k,0,n) rep(i,0,n) {
        res[i] += y[k] * temp[i];
        swap(last, temp[i]);
        temp[i] -= last * x[k];
    }
    return res;
}
```

4.2 Fourier transforms

Let $\mathbb{F}$ denote some field. Let $\mathbb{P} = \mathbb{F}[x]$ and let $\mathbb{S} = \mathbb{F}[[x]]$. Let $A = a_0 + a_1x + \dots + a_nx^n \in \mathbb{P}$ and $B = b_0 + b_1x + \dots + b_mx^m \in \mathbb{P}$.

Naive Division + Remainder of A by B :

$\mathcal{O}(nm)$ polynomial long division taught in school when $B \neq 0$.

Inverse of A: $A(0) \neq 0 \Rightarrow A^{-1} \in \mathbb{S}$. Let $T \in \mathbb{P}$ be s.t. $T(x^2) = A(x)A(-x)$. Then $A^{-1}(x) \equiv A(-x)/T(x^2) \pmod{x^j}$. To compute $A^{-1}(x) \pmod{x^j}$, we can then recursively $T^{-1}(x) \pmod{x^{\lfloor j/2 \rfloor}}$. Time complexity $\mathcal{O}(n + j \log j)$.

Hensel's lemma: Let r be a commutative ring and let $F \in r[x]$ and $a, q_0 \in r$ s.t. $F(q_0) \equiv 0 \pmod{a}$ and $F'(q_0)^{-1} \in r$. Then $F(q_1) \equiv 0 \pmod{a^2}$, where $q_1 \equiv q_0 - \frac{F(q_0)}{F'(q_0)} \pmod{a^2}$. This is useful in particular when $r = \mathbb{P}$ or $r = \mathbb{S}$.

Inverse of A: Hensel's lemma with $F(P) = A - P^{-1}$. $Q_0 \equiv a_0^{-1} \pmod{x^1}$, $Q_{j+1} \equiv Q_j(2 - AQ_j) \pmod{x^{2^{j+1}}}$. $F(Q_j) \equiv 0 \pmod{x^{2^j}}$. Still $\mathcal{O}(n + j \log j)$.

Faster Division: Given $P \in \mathbb{P}$, let P^R denote the polynomial with its coefficients reversed. If $A = DB + R$ with $\deg R < \deg B$, then $D^R \equiv A^R/B^R \pmod{x^{n-m+1}}$ and $R = A - BD$. Time complexity $\mathcal{O}((n + m) \log(n + m))$.

ln A: $(\ln A)' = A'/A$. So $\ln A = Q_0 + \int A'/A$ for some $Q_0 \in \mathbb{F}$. Intuition suggests that $Q_0 = \ln a_0$, since $\ln A(0) = Q_0 = \ln a_0$.

exp A: $Q_{k+1} \equiv Q_k(1 + A - \ln Q_k) \pmod{x^{2^{k+1}}}$.

A^j: Let $T \in \mathbb{P}$ be s.t. $T(0) = 1$ and $A(x) = \alpha x^t T(x)$ for some $\alpha \in k$. Then $A^j(x) = \alpha^j x^{jt} \exp[j \ln T(x)]$.

Chirp-Z: Given $z \in \mathbb{C}$, $s \in \mathbb{N}_{\geq 0}$. $A(z^{2^s}) = z^{s^2} \sum_{j=0}^n \left(a_j z^{j^2}\right) \left(z^{-(s-j)^2}\right)$. Clearly, $A(z^0), A(z^2), \dots, A(z^{2^s})$ can be computed in one convolution with time complexity $\mathcal{O}((s + n) \log(s + n))$. By applying $a_j \mapsto a_j z^{j^2} \forall j$, we can then apply the previous algo to compute $A(z^1), A(z^3), \dots, A(z^{2^{s+1}})$ in the same time complexity.

Multipoint-Eval: To calculate $A(x_0), \dots, A(x_{n-1})$, we use the fact that $\forall i, A(x_i) \equiv A(x) \pmod{x - x_i}$. Segment tree, segment $[l, r)$ has $P_{l,r} = \prod_{j=l}^{r-1} (x - x_j)$. We want $A_{l,r} = (A(x) \pmod{P_{l,r}})$. If $mid = \lfloor (l + r)/2 \rfloor$, then $A_{l,mid} = (A_{l,r} \pmod{P_{l,mid}})$ and $A_{mid,r} = (A_{mid,r} \pmod{P_{mid,r}})$. Finally, $A_{i,i+1} = A(x_i) \forall i$. $\mathcal{O}(n \log^2 n)$.

Interpolation: Given $(x_0, y_0), \dots, (x_{n-1}, y_{n-1})$ s.t. $x_0, \dots, x_{n-1}$ are distinct and $\forall i, A(x_i) = y_i$. Then $A(x) = \sum_{i=1}^n y_i \prod_{j \neq i} \frac{x-x_j}{x_i-x_j}$. Let $P(x) = \prod_j (x - x_j)$ and $\forall i, P_i = \prod_{j \neq i} (x_i - x_j)$. Then $P_i = P'(x_i)$, so use multipoint evaluation to compute $P_0, \dots, P_{n-1}$. Now, we recursively compute $A(x) = A_{0,n}(x)$ by letting $A_{l,r}(x) = A_{l,mid}(x) \prod_{mid \leq j < r} (x - x_j) + A_{mid,r}(x) \prod_{l \leq j < mid} (x - x_j)$. And $\forall i, A_{i,i+1}(x) = \frac{y_i}{P_i}$. Here, $mid = \lfloor (l + r)/2 \rfloor$. $\mathcal{O}(n \log^2 n)$.

GCD and Resultants: Let $\lambda_1, \dots, \lambda_n$ and $\mu_1, \dots, \mu_m$ be the roots of A and B respectively, with multiplicity. Then the resultant $\mathcal{R}(A, B) = a_n^m b_m^n \prod_{i,j} (\mu_j - \lambda_j)$. $\mathcal{R}(A, B) = (-1)^{nm} \mathcal{R}(B, A)$. $\mathcal{R}(A, B) = 0$ iff A and B share a common root. $\mathcal{R}(A, B) = a_n^m b_m^n$ when $n = 0$ or $m = 0$. $\forall C \in k[x], \mathcal{R}(A, B) = b_m^{\deg A - \deg(A - CB)} \mathcal{R}(A - CB, B)$. So, we can compute $\gcd(A, B)$ and $\mathcal{R}(A, B)$ at the same time in $\mathcal{O}(mn)$: $\mathcal{R}(A, 0) = 0$, $\mathcal{R}(A, B) = b_m^n$, $\mathcal{R}(A, B) = b_m^{\deg A - \deg D} (-1)^{\deg B \deg D} \mathcal{R}(B, D)$. Here, $D = (A \pmod{B})$. We can use this to find intersection between two curves of the form $P(x, y) = 0$ and $Q(x, y) = 0$. Let $P_{y_0}(x) = P(x, y_0) \in k[x]$ and $Q_{y_0}(x) = Q(x, y_0) \in k[x]$. First, we can solve $R(y_0) = \mathcal{R}(P_{y_0}(x), Q_{y_0}(x)) = 0$ for y_0 . Then for those y_0 , we solve $P(x, y_0) = Q(x, y_0) = 0$. Under simple circumstances, we should get finitely many intersection points.

FastFourierTransform.h

Description: fft(a) computes $\hat{f}(k) = \sum_x a[x] \exp(2\pi i \cdot kx/N)$ for all k . N must be a power of 2. Useful for convolution: conv(a, b) = c, where $c[x] = \sum a[i]b[x - i]$. For convolution of complex numbers or more than two vectors: FFT each poly, multiply result pointwise, divide by n, reverse(out.begin()+1,end), FFT back, then round(out[i].real()) or truncate out[i].imag(0). Rounding is safe if $(\sum a_i^2 + \sum b_i^2) \log_2 N < 9 \cdot 10^{14}$ (in practice 10^{16} ; higher for random inputs). Otherwise, use NTT/FFTMod.

Time: $\mathcal{O}(N \log N)$ with $N = |A| + |B|$ ($\sim 1s$ for $N = 2^{22}$)

 if (a[i][pivot] == 1) a[i] ^= x;
 a.push_back(x);
 return true;
 }
};

MatrixInverse.h
Description: Invert matrix A . Returns rank; result is stored in A unless singular (rank < n). Can easily be extended to prime moduli; for prime powers, repeatedly set $A^{-1} = A^{-1}(2I - AA^{-1}) \pmod{p^k}$ where A^{-1} starts as the inverse of A mod p , and k is doubled in each step.
Time: $\mathcal{O}(n^3)$

```
int matInv(vector<vector<double>>& A) {
    int n = sz(A); vi col(n);
    vector<vector<double>> tmp(n, vector<double>(n));
    rep(i,0,n) tmp[i][i] = 1, col[i] = i;

    rep(i,0,n) {
        int r = i, c = i;
        rep(j,i,n) rep(k,i,n)
            if (fabs(A[j][k]) > fabs(A[r][c]))
                r = j, c = k;
```

```
        if (fabs(A[r][c]) < 1e-12) return i;
        A[i].swap(A[r]); tmp[i].swap(tmp[r]);
        rep(j,0,n)
            swap(A[j][i], A[j][c]), swap(tmp[j][i], tmp[j][c]);
        swap(col[i], col[c]);
        double v = A[i][i];
        rep(j,i+1,n) {
            double f = A[j][i] / v;
            A[j][i] = 0;
            rep(k,i+1,n) A[j][k] -= f*A[i][k];
            rep(k,0,n) tmp[j][k] -= f*tmp[i][k];
        }
        rep(j,i+1,n) A[i][j] /= v;
        rep(j,0,n) tmp[i][j] /= v;
        A[i][i] = 1;
    }

    for (int i = n-1; i > 0; --i) rep(j,0,i) {
        double v = A[j][i];
        rep(k,0,n) tmp[j][k] -= v*tmp[i][k];
    }

    rep(i,0,n) rep(j,0,n) A[col[i]][col[j]] = tmp[i][j];
    return n;
}
```

Tridiagonal.h
Description:
$$\begin{pmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ \vdots \\ b_{n-1} \end{pmatrix} = \begin{pmatrix} d_0 & p_0 & 0 & 0 & \cdots & 0 \\ q_0 & d_1 & p_1 & 0 & \cdots & 0 \\ 0 & q_1 & d_2 & p_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & q_{n-3} & d_{n-2} & p_{n-2} \\ 0 & 0 & \cdots & 0 & q_{n-2} & d_{n-1} \end{pmatrix} \begin{pmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_{n-1} \end{pmatrix}$$

This is useful for solving problems on the type $a_i = b_i a_{i-1} + c_i a_{i+1} + d_i, 1 \leq i \leq n$, where a_0, a_{n+1}, b_i, c_i and d_i are known. a can then be obtained from $\{a_i\} = \text{tridiagonal}(\{1, -1, -1, \dots, -1, 1\}, \{0, c_1, c_2, \dots, c_n\}, \{b_1, b_2, \dots, b_n, 0\}, \{a_0, d_1, d_2, \dots, d_n, a_{n+1}\})$.

Fails if the solution is not unique.
If $|d_i| > |p_i| + |q_{i-1}|$ for all i , or $|d_i| > |p_{i-1}| + |q_i|$, or the matrix is positive definite, the algorithm is numerically stable and neither tr nor the check for diag[i] == 0 is needed.
Time: $\mathcal{O}(N)$

```
typedef double T;
V<T> tridiagonal(V<T> diag, const V<T>& super,
    const V<T>& sub, V<T> b) {
    int n = sz(b); vi tr(n);
    rep(i,0,n-1) {
        if (abs(diag[i]) < 1e-9 * abs(super[i])) {
            // diag[i] = 0
            b[i+1] -= b[i] * diag[i+1] / super[i];
            if (i+2 < n) b[i+2] -= b[i] * sub[i+1] / super[i];
            diag[i+1] = sub[i]; tr[++i] = 1;
        } else {
            diag[i+1] -= super[i]*sub[i]/diag[i];
            b[i+1] -= b[i]*sub[i]/diag[i];
        }
    }
```

```
    }
    for (int i = n; i--;) {
        if (tr[i]) {
            swap(b[i], b[i-1]);
            diag[i-1] = diag[i];
            b[i] /= super[i-1];
        } else {
            b[i] /= diag[i];
            if (i) b[i-1] -= b[i]*super[i-1];
        }
    }
    return b;
}
```

4.4 Optimization

GoldenSectionSearch.h

Description: Finds the argument minimizing the function f in the interval $[a,b]$ assuming f is unimodal on the interval, i.e. has only one local minimum and no local maximum. The maximum error in the result is ϵ ps. Works equally well for maximization with a small change in the code. See TernarySearch.h in the Various chapter for a discrete version.

Usage: double func(double x) { return 4+x+.3*x*x; }
double xmin = gss(-1000,1000,func);
Time: $\mathcal{O}(\log((b-a)/\epsilon))$

```
double gss(double a, double b, double (*f)(double)) {
    double r = (sqrt(5)-1)/2, eps = 1e-7;
    double x1 = b - r*(b-a), x2 = a + r*(b-a);
    double f1 = f(x1), f2 = f(x2);
    while (b-a > eps)
        if (f1 < f2) { //change to > to find maximum
            b = x2; x2 = x1; f2 = f1;
            x1 = b - r*(b-a); f1 = f(x1);
        } else {
            a = x1; x1 = x2; f1 = f2;
            x2 = a + r*(b-a); f2 = f(x2);
        }
    return a;
}
```

HillClimbing.h

Description: Poor man's optimization for unimodal functions.

```
typedef array<double, 2> P;

template<class F> pair<double, P> hillClimb(P start, F f) {
    pair<double, P> cur(f(start), start);
    for (double jmp = 1e9; jmp > 1e-20; jmp /= 2) {
        rep(j,0,100) rep(dx,-1,2) rep(dy,-1,2) {
            P p = cur.second;
            p[0] += dx*jmp;
            p[1] += dy*jmp;
            cur = min(cur, make_pair(f(p), p));
        }
    }
    return cur;
}
```

Integrate.h

Description: Simple integration of a function over an interval using Simpson's rule. The error should be proportional to h^4 , although in practice you will want to verify that the result is stable to desired precision when epsilon changes.

```
template<class F>
double quad(double a, double b, F f, const int n = 1000) {
    double h = (b - a) / 2 / n, v = f(a) + f(b);
    rep(i,1,n*2)
        v += f(a + i*h) * (i&1 ? 4 : 2);
    return v * h / 3;
}
```

IntegrateAdaptive.h

Description: Fast integration using an adaptive Simpson's rule.

Usage: double sphereVolume = quad(-1, 1, [](double x) { return quad(-1, 1, [&](double y) { return quad(-1, 1, [&](double z) { return x*x + y*y + z*z < 1; }}});});

```
typedef double d;
#define S(a,b) (f(a) + 4*f((a+b) / 2) + f(b)) * (b-a) / 6
```

```
template <class F>
d rec(F& f, d a, d b, d eps, d S) {
    d c = (a + b) / 2;
    d S1 = S(a, c), S2 = S(c, b), T = S1 + S2;
    if (abs(T - S) <= 15 * eps || b - a < 1e-10)
        return T + (T - S) / 15;
    return rec(f, a, c, eps / 2, S1) + rec(f, c, b, eps / 2, S2);
}

template<class F>
d quad(d a, d b, F f, d eps = 1e-8) {
    return rec(f, a, b, eps, S(a, b));
}
```

Simplex.h

Description: Solves a general linear maximization problem: maximize $c^T x$ subject to $Ax \leq b, x \geq 0$. Returns -inf if there is no solution, inf if there are arbitrarily good solutions, or the maximum value of $c^T x$ otherwise. The input vector is set to an optimal x (or in the unbounded case, an arbitrary solution fulfilling the constraints). Numerical stability is not guaranteed. For better performance, define variables such that $x = 0$ is viable.

Usage: vvd A = {{1,-1}, {-1,1}, {-1,-2}};
vvd b = {1,1,-4}, c = {-1,-1}, x;
T val = LPSolver(A, b, c).solve(x);

Time: $\mathcal{O}(NM * \text{\#pivots})$, where a pivot may be e.g. an edge relaxation. $\mathcal{O}(2^n)$ in the general case.

```
typedef double T; // long double, Rational, double + mod<P>...
typedef vector<T> vd;
typedef vector<vd> vvd;

Number theory (5)

5.1 Modular arithmetic

ModInverse.h

Description: Pre-computation of modular inverses. Assumes $\text{LIM} \leq \text{mod}$ and that mod is a prime.

```
const ll mod = 1000000007, LIM = 200000;
ll* inv = new ll[LIM] - 1; inv[1] = 1;
rep(i,2,LIM) inv[i] = mod - (mod / i) * inv[mod % i] % mod;
```

ModPow.h

```
const ll mod = 1000000007; // faster if const

ll modpow(ll b, ll e) {
    ll ans = 1;
    for (; e; b = b * b % mod, e /= 2)
        if (e & 1) ans = ans * b % mod;
    return ans;
}
```

ModLog.h

Description: Returns the smallest $x > 0$ s.t. $a^x = b \pmod m$, or -1 if no such x exists. modLog(a,1,m) can be used to calculate the order of a .

Time: $\mathcal{O}(\sqrt{m})$

```
ll modLog(ll a, ll b, ll m) {
    ll n = (ll) sqrt(m) + 1, e = 1, f = 1, j = 1;
    unordered_map<ll, ll> A;
    while (j <= n && (e = f = e * a % m) != b % m)
        A[e * b % m] = j++;
    if (e == b % m) return j;
    if (__gcd(m, e) == __gcd(m, b))
        rep(i,2,n+2) if (A.count(e = e * f % m))
            return n * i - A[e];
    return -1;
}
```

ModSum.h

Description: Sums of mod'ed arithmetic progressions. $\text{modsum}(\text{to}, c, k, m) = \sum_{i=0}^{\text{to}-1} (ki + c) \% m$. divsum is similar but for floored division.

Time: $\log(m)$, with a large constant.

```
typedef unsigned long long ull;
ull sumsq(ull to) { return to / 2 * ((to-1) | 1); }

ull divsum(ull to, ull c, ull k, ull m) {
    ull res = k / m * sumsq(to) + c / m * to;
    k %= m; c %= m;
    if (!k) return res;
    ull to2 = (to * k + c) / m;
    return res + (to - 1) * to2 - divsum(to2, m - 1 - c, m, k);
}

ll modsum(ull to, ll c, ll k, ll m) {
    c = ((c % m) + m) % m;
    k = ((k % m) + m) % m;
    return to * c + k * sumsq(to) - m * divsum(to, c, k, m);
}
```

ModMulLL.h

Description: Calculate $a \cdot b \bmod c$ (or $a^b \bmod c$) for $0 \leq a, b \leq c \leq 7.2 \cdot 10^{18}$.

Time: $\mathcal{O}(1)$ for modmul, $\mathcal{O}(\log b)$ for modpow

bbbd8f, 11 lines

```
typedef unsigned long long ull;
ull modmul(ull a, ull b, ull M) {
    ll ret = a * b - M * ull(1.L / M * a * b);
    return ret + M * (ret < 0) - M * (ret >= (1l
        )M);
}
ull modpow(ull b, ull e, ull mod) {
    ull ans = 1;
    for (; e; b = modmul(b, b, mod), e /= 2)
        if (e & 1) ans = modmul(ans, b, mod);
    return ans;
}
```

ModSqrt.h

Description: Tonelli-Shanks algorithm for modular square roots. Finds x s.t. $x^2 = a \pmod p$ ($-x$ gives the other solution).

Time: $\mathcal{O}(\log^2 p)$ worst case, $\mathcal{O}(\log p)$ for most p

"ModPow.h"

        x = x * gs % p;
        b = b * g % p;
    }
}
```

LinearSieve.h

Description: Can be used to precompute multiplicative functions using $f(px) = f(p)f(x)$ when $p \nmid x$. We compute $f(px) = f(p^{e+1} \cdot x/p^e) = f(p^{e+1})f(x/p^e)$ by multiplicativity (bookkeeping e , the max power of p dividing x where p is the smallest prime dividing x). If $f(px)$ can be computed easily when $p \mid x$ then we can simplify the code.

Time: $\mathcal{O}(n)$

e696bd, 16 lines

```
int func[N],cnt[N]; bool isc[N]; V<int> prime;
void sieve(int n) {
    fill(isc, isc + n, false); func[1] = 1;
    for (int i = 2; i < n; ++i) {
        if (!isc[i]) {
            prime.push_back(i); func[i]=1; cnt[i]=1;
        }

                    prime[j]];
                cnt[i * prime[j]] = 1;
            }
        }
    }
}
```

phiFunction.h

Description: Euler's ϕ function is defined as $\phi(n) := \#$ of positive integers $\leq n$ that are coprime with n . $\phi(1) = 1$, p prime $\Rightarrow \phi(p^k) = (p-1)p^{k-1}$, m, n coprime $\Rightarrow \phi(mn) = \phi(m)\phi(n)$. If $n = p_1^{k_1} p_2^{k_2} \dots p_r^{k_r}$ then $\phi(n) = (p_1-1)p_1^{k_1-1} \dots (p_r-1)p_r^{k_r-1}$. $\phi(n) = n \cdot \prod_{p|n} (1-1/p)$. $\sum_{d|n} \phi(d) = n$, $\sum_{1 \leq k \leq n, \gcd(k,n)=1} k = n\phi(n)/2$, $n > 1$.

Euler's thm: a, n coprime $\Rightarrow a^{\phi(n)} \equiv 1 \pmod n$.

Fermat's little thm: p prime $\Rightarrow a^{p-1} \equiv 1 \pmod p, \forall a$.

    return x < 0 ? x + m*n/g : x;
}

5.3.1 Bézout's identity
For  $a \neq 0, b \neq 0$ , then  $d = \gcd(a, b)$  is the smallest positive integer for which there are integer solutions to  $ax + by = d$ . If  $(x, y)$  is one solution, then all solutions are given by  $(x + kb/d, y - ka/d)$ ,  $k \in \mathbb{Z}$ . Find one solution using egcd.
```

FracBinarySearch.h

Description: Given f and N , finds the smallest fraction $p/q \in [0, 1]$ such that $f(p/q)$ is true, and $p, q \leq N$. You may want to throw an exception from f if it finds an exact solution, in which case N can be removed.

Usage: `fracBS([](Frac f) { return f.p>=3*f.q; }, 10);` // {1,3}

Time: $\mathcal{O}(\log(N))$

27ab3e, 25 lines

```
struct Frac { ll p, q; };

template<class F>
Frac fracBS(F f, ll N) {
    bool dir = 1, A = 1, B = 1;
    Frac lo{0, 1}, hi{1, 1}; // Set hi to 1/0 to
        search (0, N]
    if (f(lo)) return lo;
    assert(f(hi));
    while (A || B) {
        ll adv = 0, step = 1; // move hi if dir,
            else lo
        for (int si = 0; step; (step *= 2) >= si)
            {
                adv += step;
                Frac mid{lo.p * adv + hi.p, lo.q * adv +
                    hi.q};
                if (abs(mid.p) > N || mid.q > N || dir
                    == !f(mid)) {
                    adv -= step; si = 2;
                }
            }
        hi.p += lo.p * adv;
        hi.q += lo.q * adv;
        dir = !dir;
        swap(lo, hi);
        A = B; B = !adv;
    }
    return dir ? hi : lo;
}
```

Mobius Function

$$\mu(n) = \begin{cases} 0 & n \text{ is not square free} \\ 1 & n \text{ has even number of prime factors} \\ -1 & n \text{ has odd number of prime factors} \end{cases}$$

Mobius Inversion:

$$g(n)=\sum_{d|n}f(d)\Leftrightarrow f(n)=\sum_{d|n}\mu(d)g(n/d)$$

Other useful formulas/forms:

$$\sum_{d|n}\mu(d)=[n=1],\phi(n)=\sum_{d|n}\mu(d)\frac{n}{d}$$

$$g(n)=\sum_{n|d}f(d)\Leftrightarrow f(n)=\sum_{n|d}\mu(\frac{d}{n})g(d)$$

$$g(n)=\sum_{1\leq m\leq n}f(\lfloor\frac{n}{m}\rfloor)\Leftrightarrow f(n)=\sum_{1\leq m\leq n}\mu(m)g(\lfloor\frac{n}{m}\rfloor)$$

If f multiplicative,
 $\sum_{d|n}\mu(d)f(d)=\prod_{\text{prime } p|n}(1-f(p))$ and
 $\sum_{d|n}\mu^2(d)f(d)=\prod_{\text{prime } p|n}(1+f(p))$.

If $s_f(n)=\sum_{i=1}^nf(i)$ is a prefix sum of
multiplicative f then $s_{f*g}(n)=\sum_{1\leq xy\leq n}f(x)g(y)$.
Then $s_f(n)=\{s_{f*g}(n)-\sum_{d=2}^ns_f(\lfloor n/d\rfloor)g(d)\}/g(1)$
where $f*g(n)=\sum_{d|n}f(d)g(n/d)$ (Dirichlet).

Precompute (linear sieve) $O(n^{2/3})$ first values of s_f
for complexity $O(n^{2/3})$.

Useful sums and convolutions: $\epsilon=\mu*1$, $\text{id}=\phi*1$,
 $\text{id}=g*\text{id}_2$, where $\epsilon(n)=[n=1]$, $1(n)=1$,
 $\text{id}(n)=n$, $\text{id}_k(n)=n^k$,
 $g(n)=\sum_{d|n}\mu(d)nd$.

coprime pairs in $[1,n]$ is $\sum_{d=1}^n\mu(d)\lfloor n/d\rfloor^2$. Sum of
GCD pairs in $[1,n]$ is $\sum_{d=1}^n\phi(d)\lfloor n/d\rfloor^2$. Sum of
LCM pairs in $[1,n]$ is $\sum_{d=1}^n(\frac{\lfloor n/d\rfloor(1+\lfloor n/d\rfloor)}{2})^2g(d)$,
where g is defined above with
 $g(p^k)=p^k-p^{k+1}$.

Combinatorial (6)

6.1 Permutations

IntPerm.h
Description: Permutation -> integer conversion. (Not
order preserving.) Integer -> permutation can use a
lookup table.
Time: $\mathcal{O}(n)$

```
044568, 6 lines
int permToInt(vi& v) {
    int use = 0, i = 0, r = 0;
    for(int x:v) r = r * ++i +
        __builtin_popcount(use & -(1<<x)),
        use |= 1 << x; // (note: minus, not ~!)
    return r;
}
```

multinomial.h
Description: Computes $\binom{v_0+\dots+v_{n-1}}{v_0,\dots,v_{n-1}}$

```
a0a312, 6 lines
ll multinomial(vi& v) {
    ll c = 1, m = v.empty() ? 1 : v[0];
    rep(i,1,sz(v)) rep(j,0,v[i])
        c = c * +m / (j+1);
    return c;
}
```

Cycles Let $g_S(n)$ be the number of n -permutations
whose cycle lengths all belong to the set S . Then
 $\sum_{n\geq 0}g_S(n)\frac{x^n}{n!}=\exp\left(\sum_{n\in S}\frac{x^n}{n}\right)$
Derangements Permutations of a set such that
none of the elements appear in their original
position. $D(n)=(n-1)(D(n-1)+D(n-2))=$
 $nD(n-1)+(-1)^n=\left\lfloor\frac{n!}{e}\right\rfloor$

Burnside’s Lemma Given a group G of
symmetries and a set X , the number of elements of
 X up to symmetry equals $\frac{1}{|G|}\sum_{g\in G}|X^g|$, where X^g
are the elements fixed by g ($g\cdot x=x$). If $f(n)$ counts
“configurations” (of some sort) of length n , we can
ignore rotational symmetry using $G=\mathbb{Z}_n$ to get
 $g(n)=\frac{1}{n}\sum_{k=0}^{n-1}f(\gcd(n,k))=$
 $\frac{1}{n}\sum_{k|n}f(k)\phi(n/k)$.

Partition function Number of ways of writing n as
a sum of positive integers, disregarding the order of
the summands. $p(0)=1$,
 $p(n)=\sum_{k\in\mathbb{Z}\setminus\{0\}}(-1)^{k+1}p(n-k(3k-1)/2)$.
 $p(n)\sim 0.145/n\cdot\exp(2.56\sqrt{n})$
First few values: 1, 1, 2, 3, 5, 7, 11, 15, 22, 30.
 $p(20)=627$, $p(50)\approx 2e5$, $p(100)\approx 2e8$.

Lucas’ Theorem: Let n, m be non-negative
integers and p a prime. Write
 $n=n_kp^k+\dots+n_1p+n_0$ and
 $m=m_kp^k+\dots+m_1p+m_0$. Then
 $\binom{n}{m}=\prod_{i=0}^k\binom{n_i}{m_i}\pmod p$.
Bernoulli numbers EGF of Bernoulli numbers is
 $B(t)=\frac{t}{e^t-1}$ (FFT-able). $\sum\frac{B_i}{i!}x^i=\frac{x}{1-e^{-x}}$.
 $B[0,\dots]=[1,-\frac{1}{2},\frac{1}{6},0,-\frac{1}{30},0,\frac{1}{42},\dots]$.
Sums of powers:

$$\sum_{i=1}^nn^m=\frac{1}{m+1}\sum_{k=0}^m\binom{m+1}{k}B_k\cdot(n+1)^{m+1-k}$$

Stirling numbers of the first kind Number of
permutations on n items with k cycles.
 $c(n,k)=c(n-1,k-1)+(n-1)c(n-1,k)$,
 $c(0,0)=1$. $\sum_{k=0}^nc(n,k)x^k=x(x+1)\dots(x+n-1)$
 $c(8,k)=$
8, 0, 5040, 13068, 13132, 6769, 1960, 322, 28, 1
 $c(n,2)=$
0, 0, 1, 3, 11, 50, 274, 1764, 13068, 109584, ..

Stirling numbers of the second kind Partitions
of n distinct elements into exactly k non-empty
subsets. $S(n,k)=S(n-1,k-1)+kS(n-1,k)$.
 $S(n,1)=S(n,n)=1$.
 $S(n,k)=\frac{1}{k!}\sum_{j=0}^k(-1)^{k-j}\binom{k}{j}j^n$.

Eulerian numbers Number of n -permutations
with exactly k rises (positions i with $p_i>p_{i-1}$).
 $E(n,k)=(n-k)E(n-1,k-1)+(k+1)E(n-1,k)$.
 $E(n,0)=E(n,n-1)=1$.
 $E(n,k)=\sum_{j=0}^k(-1)^j\binom{n+1}{j}(k+1-j)^n$.

Bell numbers Total number of partitions of n
distinct elements. $B(n)=$
1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147,
 $B(3)=5=\{a|b|c,a|bc,b|ac,c|abc,abc\}$. For p prime,
 $B(p^m+n)\equiv mB(n)+B(n+1)\pmod p$.

Catalan numbers
 $C_n=\frac{1}{n+1}\binom{2n}{n}=\binom{2n}{n}-\binom{2n}{n+1}=\frac{(2n)!}{(n+1)!n!}$
 $C_0=1$, $C_{n+1}=\frac{2(2n+1)}{n+2}C_n$, $C_{n+1}=\sum C_iC_{n-i}$
 $C_n=1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, \dots$
- UR path from $(0,0)$ to (n,n) below $y=x$.
- strings with n pairs of parenthesis, correctly
nested.
- binary trees with with $n+1$ leaves (0 or 2
children).
- ordered trees with $n+1$ vertices.
- ways a convex polygon with $n+2$ sides can be cut
into triangles by connecting vertices with straight
lines.
- permutations of $[n]$ with no 3-term increasing
subseq.

Labeled unrooted trees: # on n vertices:
 n^{n-2}
on k existing trees of size n_i :
 $n_1n_2\dots n_kn^{k-2}$
with degrees d_i :
 $(n-2)!/((d_1-1)!\dots(d_n-1)!)$
ways to connect k components with $k-1$ edges:
 $s_1\dots s_k\cdot n^{k-2}$
Number of Spanning Trees Create an $N\times N$
matrix mat , and for each edge $a\rightarrow b\in G$, do
 $\text{mat}[a][b]--$, $\text{mat}[b][b]++$ (and $\text{mat}[b][a]--$,
 $\text{mat}[a][a]++$ if G is undirected). Remove the i th
row and column and take the determinant; this
yields the number of directed spanning trees rooted
at i (if G is undirected, remove any
row/column).
Erdős–Gallai theorem A simple graph with node
degrees $d_1\geq\dots\geq d_n$ exists iff $d_1+\dots+d_n$ is even
and for every $k=1\dots n$,

$$\sum_{i=1}^kd_i\leq k(k-1)+\sum_{i=k+1}^n\min(d_i,k).$$

Sprague-Grundy Theorem: Viewing the game as
a DAG, where a player moves from one node v to
any neighbor v_i , the Grundy value $G(v)=\text{mex}\{v_i\}$
gives an equivalent pile of nim. If the game breaks
into several equivalent games where player can move
at any single part, take xorsum to combine (just like
nim). Use DP/pattern hunting.

Graph (7)

7.1 Shortest Paths

BellmanFord.h
Description: Calculates shortest paths from s in a
graph that might have negative edge weights. Un-
reachable nodes get $\text{dist}=\text{inf}$; nodes reachable through
negative-weight cycles get $\text{dist}=-\text{inf}$. Assumes
 $V^2\max|w_i|\leq 2^{63}$.
Time: $\mathcal{O}(VE)$

```
830a8f, 23 lines
const ll inf = LLONG_MAX;
struct Ed { int a, b, w, s() { return a < b ?
    a : -a; }};
struct code { ll dist = inf; int prev = -1; };
```

```
void bellmanFord(vector<Node>& nodes, vector<
    Ed>& eds, int s) {
    nodes[s].dist = 0;
    sort(all(eds), [](Ed a, Ed b) { return a.s()
        < b.s(); });

    int lim = sz(nodes) / 2 + 2; // /3+100 with
        shuffled vertices
    rep(i,0,lim) for (Ed ed : eds) {
        Node cur = nodes[ed.a], &dest = nodes[ed.b]
            ;
        if (abs(cur.dist) == inf) continue;
        ll d = cur.dist + ed.w;
        if (d < dest.dist) {
            dest.prev = ed.a;
            dest.dist = (i < lim-1 ? d : -inf);
        }
    }
    rep(i,0,lim) for (Ed e : eds) {
        if (nodes[e.a].dist == -inf)
            nodes[e.b].dist = -inf;
    }
}
```

FloydWarshall.h

Description: Calculates all-pairs shortest path in a di-
rected graph that might have negative edge weights. In-
put is an distance matrix m , where $m[i][j]=\text{inf}$ if i and
 j are not adjacent. As output, $m[i][j]$ is set to the short-
est distance between i and j , inf if no path, or $-\text{inf}$ if
the path goes through a negative-weight cycle.
Time: $\mathcal{O}(N^3)$

```
531245, 12 lines
const ll inf = 1LL << 62;
void floydWarshall(vector<vector<ll>>& m) {
    int n = sz(m);
    rep(i,0,n) m[i][i] = min(m[i][i], 0LL);
    rep(k,0,n) rep(i,0,n) rep(j,0,n)
        if (m[i][k] != inf && m[k][j] != inf) {
            auto newDist = max(m[i][k] + m[k][j], -
                inf);
            m[i][j] = min(m[i][j], newDist);
        }
    rep(k,0,n) if (m[k][k] < 0) rep(i,0,n) rep(j
        ,0,n)
        if (m[i][k] != inf && m[k][j] != inf) m[i
            ][j] = -inf;
}
```

Johnson.h

Description: APSP on weighted directed graphs with
no negative cycles. Add a dummy node q connected by
0-weighted edge to each other node. Then run Bell-
man from q to find minimum weight $h(v)$ of a path
 $q\rightsquigarrow v$ (terminate if negative cycle found). Next, reweight
the original graph: $\forall u\rightarrow v$ with weight $w(u,v)$, as-
sign new weight $w(u,v)+h(u)-h(v)$. Now $D(u,v)=$
 $\text{Dijkstra}(u,v)+h(v)-h(u)$.
Time: $\mathcal{O}(\text{Bellman})+\mathcal{O}(V)*\mathcal{O}(\text{Dijkstra})$

7.2 Network flow

Dinic.h
Description: Flow algorithm. with complexity
Time: $\mathcal{O}(VE\log U)$ where $U=\max|\text{cap}|$.
 $\mathcal{O}\left(\min(E^{1/2},V^{2/3})E\right)$ if $U=1$; $\mathcal{O}\left(\sqrt{VE}\right)$ for
bipartite matching.

    return tree;
}
```

7.2.1 Flow Variations
Demand Flow: Each node has an associated $d(v) = f_{in}(v) - f_{out}(v)$. So $d(v) > 0$ means node wishes to receive more. Given $d(v)$'s for each vertex the problem is to figure out whether it is possible to satisfy all demands while maintaining capacity constraints. Solution - First check $\sum d(v) = 0$. Next add a source S and sink T. Now for each $d(v) < 0$, add edge $S \rightarrow v$ with capacity $-d(v)$, and for each $d(v) > 0$, add edge $v \rightarrow T$ with capacity $d(v)$. Now maxflow = $\sum_{d(v) > 0} d(v)$ guarantees that solution exists.
Circulations with demands and lower bounds: Each edge now has a lower bound $l(e)$, so the capacity constraint is now $0 \leq l(e) \leq f(e) \leq c(e)$. Also, each vertex has demand $d(v)$. Solution - Split flow into two parts f_0, f_1 . Let $f_0(e) = l(e)$ for each edge, thus the lower bound condition is satisfied. Now satisfy the demand conditions by setting new demand $d'(v) = d(v) - F(v)$, where $F(v) = \sum_{(x,v)} l(x,v) - \sum_{(v,x)} l(v,x)$. Also set new upperbounds to $c(e) - l(e)$.
Max flow with lower bound (no demands): Binary search on max flow F. Add edge $T \rightarrow S$ with bounds $[F, \infty]$, and set all $d(v) = 0$. Now feasibility implies that a construction with at least F flow exists.
Project Selection Problem: Add source S and sink T. For each project P_i with profit p_i , add $S \rightarrow P_i$ with capacity p_i . For each machine M_i with cost to buy c_i , add $M_i \rightarrow T$ with capacity c_i . For each machines required for a project, add edge $P_i \rightarrow M_j$ with capacity ∞ . Now, $\sum p_i$ - mincut gives the maximum profit.

7.3 Matching

HopcroftKarp.h

Description: Fast bipartite matching algorithm. Graph *g* should be a list of neighbors of the left partition, and *btoa* should be a vector full of -1's of the same size as the right partition. Returns the size of the matching. *btoa[i]* will be the match for vertex *i* on the right side, or -1 if it's not matched.

Usage: vi btoa(m, -1); hopcroftKarp(g, btoa);

Time: $\mathcal{O}(\sqrt{VE})$

	728df7, 34 lines
--	------------------

```
bool dfs(int a, int L, vector<vi>& g, vi& btoa, vi& A, vi& B) {

7.4 DFS algorithms

SCC.h

Description: Finds strongly connected components in a directed graph. If vertices *u, v* belong to the same component, we can reach *u* from *v* and vice versa.

Usage: scc(graph, [&](vi& v) { ... }) visits all components

in reverse topological order. comp[i] holds the component index of a node (a component only has edges to components with lower index). ncomps will contain the number of components.

Time: $\mathcal{O}(E + V)$

76b5c9, 21 lines

```
vi val, comp, z, cont;
int Time, ncomps; template<class G, class F>
int dfs(int j, G& g, F& f) {
    int low=val[j]=++Time, x; z.push_back(j);
    for (auto e : g[j]) if (comp[e] < 0)
        low = min(low, val[e] ? : dfs(e,g,f));
    if (low == val[j]) {
        do {
            x = z.back(); z.pop_back();
            comp[x] = ncomps; cont.push_back(x);
        } while (x != j);
        f(cont); cont.clear(); ncomps++;
    }
    return val[j] = low;
}
template<class G,class F> void scc(G& g, F f){
    int n = sz(g);
    val.assign(n, 0); comp.assign(n, -1);
    Time = ncomps = 0;
    rep(i,0,n) if (comp[i] < 0) dfs(i, g, f);
}
```

BiconnectedComponents.h

Description: Finds all biconnected components in an undirected graph, and runs a callback for the edges in each. In a biconnected component there are at least two distinct paths between any two nodes. Note that a node can be in several components. An edge which is not in a component is a bridge. A node is a cut point if (1) Exists in multiple bccs, or (2) Endpoint of a bridge with degree > 1 (self loops don't count as degree).

Usage: int eid = 0; g.resize(N);

for each edge (a,b) {

g[a].emplace_back(b, eid);

g[b].emplace_back(a, eid++); }

bicomps([&](const vi& edgelist) {...});

Time: $\mathcal{O}(E + V)$

c5905f, 26 lines

```

            } else { id[u] = x; }
        }
    }
}
int main() {
    for (int i = 1; i <= n; ++i)
        if (!in[i]) dfs(i);
    buildTree();
}
```

2sat.h
Description: Calculates a valid assignment to boolean variables a, b, c,... to a 2-SAT problem, so that an expression of the type (a||b)&&(!a||c)&&(d||b)&&... becomes true, or reports that it is unsatisfiable. Negated variables are represented by bit-inversions (~x).
Usage: TwoSat ts(number of boolean variables);
ts.either(0, ~3); // Var 0 is true or var 3 is false
ts.setValue(2); // Var 2 is true
ts.atMostOne({0,~1,2}); // <= 1 of vars 0, ~1 and 2 are true
ts.solve(); // Returns true iff it is solvable
ts.values[0..N-1] holds the assigned values to the vars
Time: $\mathcal{O}(N + E)$, where N is the number of boolean variables, and E is the number of clauses.

```

CompressTree.h

Description: Given a rooted tree and a subset S of nodes, compute the minimal subtree that contains all the nodes by adding all (at most $|S| - 1$) pairwise LCA's and compressing edges. Returns a list of (par, orig_index) representing a tree rooted at 0. The root points to itself.

Time: $\mathcal{O}(|S| \log |S|)$

```

HLD-easy.h

Description: Subtree of v: $[in_v, out_v]$. Path from v to the last vertex in ascending heavy path from v (which is nxt_v) will be in $[in_{nxt_v}, in_v]$.

Usage: each $g[u]$ must not contain the parent. call `dfs.sz()`, then `dfs.hld()`. Be careful about switching to 1-indexing.

```
430255, 12 lines

void dfs_sz(int u = 0) { sz[u] = 1;
    for(auto &v: g[u]) {
        dfs_sz(v); sz[u] += sz[v];
        if(sz[v] > sz[g[u][0]]) swap(v, g[u][0]);
    }
}

void dfs_hld(int u = 0) { in[u] = t++;
    for(auto v: g[u]) {
        nxt[v] = (v == g[u][0] ? nxt[u] : v);
        dfs_hld(v);
```

```
    } out[u] = t;
}
```

HLD-ruhan.h

Description: 0-based indexing, HLDSegTree refers to the type of the segment tree The segment tree must have `update(l, r, +dx)` and `query(l, r)` methods.

Time: $\mathcal{O}((\log N)^2)$ (not sure about this, though)

TreeBinarize.h
Description: Given a weighted tree in edge-listing representation, transforms it into a binary tree by adding at most $2n$ extra nodes.
Usage: call add_edge() for both directions to create the tree. Then call binarize(1). Will change n.

```
// N = 3 * max nodes, M = 2 * N
int n, o = 2;
int to[M],wgt[M],prv[M],nxt[M],lst[N],deg[N];
```

```
void add_edge(int u, int v, int w) {
    to[o] = v, wgt[o] = w, deg[v]++;
    prv[o] = lst[u], lst[u] = nxt[lst[u]] = o++;
}

void binarize(int u, int f = 0) {
    int d = deg[u] - 2 - (f != 0);
    if (d > 0) {
        int tmp_lst = (to[lst[u]] == f ? prv[lst[u]] : lst[u]), x;
        for (int e = lst[u], at = n+d; at > n; ){
            x = prv[e];
```

```
            if (to[e] == f) { e = x; continue; }
            nxt[x] = nxt[e];
            nxt[e] ? prv[nxt[e]] = x : lst[u] = x;
            prv[e] = lst[at], nxt[e] = 0;
            lst[at] = nxt[lst[at]] = e, deg[at]++;
            to[e ^ 1] = at;
            if (e != tmp_lst) --at;
            e = x;
        }
        for (int i=1, p=u; i <= d; p = n + i++)
            add_edge(p, n + i, 0);
            add_edge(n + i, p, 0);
            n += d, deg[u] -= d + 1;
    }
    for (int e = lst[u]; e; e = prv[e])
        if (to[e] != f) binarize(to[e], u);
}
```

CentroidDecomp.h
Description: Divide and conquer on trees. Useful for solving problems regarding all pairs of paths. Simple modifications are needed to integrate TreeBinarize into this.
Usage: Just call decompose(1). ctp[u] = parent of u in ctree. cth[u] = height of u in ctree, root has height = 1. dist[u][h] = original tree distance (u -> ctree ancestor of u at height h).
Time: $\mathcal{O}(N \lg N)$

```
// H = -lg(N), reset: cth, ctp, dist
int sub[N], cth[N], ctp[N], dist[N][H + 1];
void dfs_siz(int u, int f) {
    sub[u] = 1;
    for (int v : g[u]) if (!cth[v] && v ^ f)
        dfs_siz(v, u), sub[u] += sub[v];
}

};
```

lineEquation.h
Description: Gives normalized line equation $ax + by = c$, passing through points p and q.
tuple<ll,ll,ll> get_line_eq (Point p, Point q)
{
Point normal = (q - p).perp();
if (normal.x < 0) {
normal.x *= -1;
normal.y *= -1;
} else if (normal.x == 0 && normal.y < 0) {
normal.y *= -1;
} // ax + by = c
ll c = normal.dot(p);
ll g = gcd(c, gcd(normal.x, normal.y));
return {normal.x / g, normal.y / g, c / g};
}

lineDistance.h
Description: Returns the signed distance between point p and the line containing points a and b. Positive value on left side and negative on right as seen from a towards b. a==b gives nan. P is supposed to be Point<T> or Point3D<T> where T is e.g. double or long long. It uses products in intermediate steps so watch out for overflow if using int or long long. Using Point3D will always give a non-negative distance. For Point3D, call .dist on the result of the cross product.

```

Point.h"
f6bf6b, 4 lines
template<class P>
```

```
double lineDist(const P& a, const P& b, const P& p) {
    return (double) (b-a).cross(p-a) / (b-a).dist()
};
```

    return q0 + P((r-p0).cross(num), (r-p0).dot(
        num))/dp.dist2();
}
```

LineProjectionReflection.h

Description: Projects point p onto line ab. Set refl=true to get reflection of point p across line ab instead. The wrong point will be returned if P is an integer point and the desired point doesn't have integer coordinates. Products of three coordinates are used in intermediate steps so watch out for overflow.

```
"Point.h" b5562d, 5 lines

template<class P>
P lineProj(P a, P b, P p, bool refl=false) {
    P v = b - a;
    return p - v.perp()*(1+refl)*v.cross(p-a)/v.
        dist2();
}
```

Angle.h

Description: A class for ordering angles (as represented by int points and a number of rotations around the origin). Useful for rotational sweeping. Sometimes also represents points or vectors.

Usage: vector<Angle> v = {w[0], w[0].t360()...}; // sorted
int j = 0; rep(i,0,n) { while (v[j] < v[i].t180()) ++j; }
// sweeps j such that (j-i) represents the number of positively oriented triangles with vertices at 0 and i

```

}
```

8.2 Circles

CircleIntersection.h

Description: Computes the pair of points at which two circles intersect. Returns false in case of no intersection.

```
"Point.h" 84d6d3, 11 lines

typedef Point<double> P;
bool circleInter(P a,P b,double r1,double r2,
    pair<P, P>* out) {
    if (a == b) { assert(r1 != r2); return false
        ; }
    P vec = b - a;
    double d2 = vec.dist2(), sum = r1+r2, dif =
        r1-r2,
        p = (d2 + r1*r1 - r2*r2)/(d2*2), h2 =
            r1*r1 - p*p*d2;
    if (sum*sum < d2 || dif*dif > d2) return
        false;
    P mid = a + vec*p, per = vec.perp() * sqrt(
        fmax(0, h2) / d2);
    *out = {mid + per, mid - per};
    return true;
}
```

CircleTangents.h

Description: Finds the external tangents of two circles, or internal if r2 is negated. Can return 0, 1, or 2 tangents – 0 if one circle contains the other (or overlaps it, in the internal case, or if the circles are the same); 1 if the circles are tangent to each other (in which case .first = .second and the tangent line is perpendicular to the line between the centers). .first and .second give the tangency points at circle 1 and 2 respectively. To find the tangents of a circle with a point set r2 to 0.

```
"Point.h" b0153d, 13 lines

template<class P>
```

```
vector<pair<P, P>> tangents(P c1, double r1, P
    c2, double r2) {
    P d = c2 - c1;
    double dr = r1 - r2, d2 = d.dist2(), h2 = d2
        - dr * dr;
    if (d2 == 0 || h2 < 0) return {};
    vector<pair<P, P>> out;
    for (double sign : {-1, 1}) {
        P v = (d * dr + d.perp() * sqrt(h2) * sign
            ) / d2;
        out.push_back({c1 + v * r1, c2 + v * r2});
    }
    if (h2 == 0) out.pop_back();
    return out;
}
```

CircleLine.h

Description: Finds the intersection between a circle and a line. Returns a vector of either 0, 1, or 2 intersection points. P is intended to be Point<double>.

```
"Point.h" e0cfba, 9 lines

template<class P>
vector<P> circleLine(P c, double r, P a, P b)
{
    P ab = b - a, p = a + ab * (c-a).dot(ab) /
        ab.dist2();
    double s = a.cross(b, c), h2 = r*r - s*s /
        ab.dist2();
    if (h2 < 0) return {};
    if (h2 == 0) return {p};
    P h = ab.unit() * sqrt(h2);
    return {p - h, p + h};
}
```

CirclePolygonIntersection.h

Description: Returns the area of the intersection of a circle with a ccw polygon.

Time: $\mathcal{O}(n)$

```
".../content/geometry/Point.h" aleec63, 19 lines

typedef Point<double> P;

            }
        }
    }
    return {o, r};
}
```

8.3 Polygons

InsidePolygon.h
Description: Returns true if p lies within the polygon. If strict is true, it returns false for points on the boundary. The algorithm uses products in intermediate steps so watch out for overflow.
Usage: vector<P> v = {P{4,4}, P{1,2}, P{2,1}}; bool in = inPolygon(v, P{3, 3}, false);
Time: $\mathcal{O}(n)$

```
"Point.h", "OnSegment.h", "SegmentDistance.h" 2bf504, 11 lines
template<class P>
bool inPolygon(vector<P> &p, P a, bool strict = true) {
    int cnt = 0, n = sz(p);
```

```
rep(i,0,n) {
    P q = p[(i + 1) % n];
    if (onSegment(p[i], q, a)) return !strict;
    //or: if (segDist(p[i], q, a) <= eps) return !strict;
    cnt ^= ((a.y<p[i].y) - (a.y<q.y)) * a.cross(p[i], q) > 0;
}
return cnt;
}
```

PolygonArea.h
Description: Returns twice the signed area of a polygon. Clockwise enumeration gives negative area. Watch out for overflow if using int as T!

```
"Point.h" f12300, 6 lines
template<class T>
T polygonArea2(vector<Point<T>& v) {
    T a = v.back().cross(v[0]);
    rep(i,0,sz(v)-1) a += v[i].cross(v[i+1]);
    return a;
}
```

PolygonCenter.h
Description: Returns the center of mass for a polygon.
Time: $\mathcal{O}(n)$

```
"Point.h" 9706dc, 9 lines
typedef Point<double> P;
P polygonCenter(const vector<P>& v) {
    P res(0, 0); double A = 0;
    for (int i = 0, j = sz(v) - 1; i < sz(v); j = i++) {
        res = res + (v[i] + v[j]) * v[j].cross(v[i+1]);
        A += v[j].cross(v[i]);
    }
    return res / A / 3;
}
```

PolygonCut.h
Description:
Returns a vector with the vertices of a polygon with everything to the left of the line going from s to e cut away.

Usage: vector<P> p = ...; p = polygonCut(p, P(0,0), P(1,0));

```
"Point.h", "lineIntersection.h" f2b7d4, 13 lines
typedef Point<double> P;
vector<P> polygonCut(const vector<P>& poly, P s, P e) {
    vector<P> res;
    rep(i,0,sz(poly)) {

        rep(j,1,sz(segs)) {
            if (!cnt) sum += segs[j].first - segs[j-1].first;
            cnt += segs[j].second;
        }
        ret += A.cross(B) * sum;
    }
    return ret / 2;
}
```

ConvexHull.h
Description:
Returns a vector of the points of the convex hull in counter-clockwise order. Points on the edge of the hull between two other points are not considered part of the hull.

Time: $\mathcal{O}(n \log n)$

```
"Point.h" 310954, 13 lines
typedef Point<ll> P;
vector<P> convexHull(vector<P> pts) {
    if (sz(pts) <= 1) return pts;
    sort(all(pts));
    vector<P> h(sz(pts)+1);
    int s = 0, t = 0;
    for (int it = 2; it--; s = --t, reverse(all(pts)))
        for (P p : pts) {
            while (t >= s + 2 && h[t-2].cross(h[t-1], p) <= 0) t--;
            h[t++] = p;
        }
    return {h.begin(), h.begin() + t - (t == 2 && h[0] == h[1])};
}
```

HullDiameter.h
Description: Returns the two points with max distance on a convex hull (ccw, no duplicate/collinear points).
Time: $\mathcal{O}(n)$

```
"Point.h" c571b8, 12 lines
typedef Point<ll> P;
array<P, 2> hullDiameter(vector<P> S) {
    int n = sz(S), j = n < 2 ? 0 : 1;
    pair<ll, array<P, 2>> res({0, {S[0], S[0]}});

    }
    return sgn(l[a].cross(l[b], p)) < r;
}
```

LineHullIntersection.h

Description: Line-convex polygon intersection. The polygon must be ccw and have no collinear points. lineHull(line, poly) returns a pair describing the intersection of a line with the polygon: $\bullet (-1, -1)$ if no collision, $\bullet (i, -1)$ if touching the corner i , $\bullet (i, i)$ if along side $(i, i + 1)$, $\bullet (i, j)$ if crossing sides $(i, i + 1)$ and $(j, j + 1)$. In the last case, if a corner i is crossed, this is treated as happening on side $(i, i + 1)$. The points are returned in the same order as the line hits the polygon. extrVertex returns the point of a hull with the max projection onto a line.

Time: $\mathcal{O}(\log n)$

```
"Point.h" 7cf45b, 39 lines

#define cmp(i, j) sgn(dir.perp().cross(poly[(i) % n] - poly[(j) % n]))

FastDelaunay.h

Description: Fast Delaunay triangulation. Each circumcircle contains none of the input points. There must be no duplicate points. If all points are on a line, no triangles will be returned. Should work for doubles as well, though there may be precision issues in 'circ'. Returns triangles in order {t[0][0], t[0][1], t[0][2], t[1][0], ...}, all counter-clockwise.

Time: $\mathcal{O}(n \log n)$

```

```

sphericalDistance.h

Description: Returns the shortest distance on the sphere with radius radius between the points with azimuthal angles (longitude) f1 (ϕ_1) and f2 (ϕ_2) from x axis and zenith angles (latitude) t1 (θ_1) and t2 (θ_2) from z axis (0 = north pole). All angles measured in radians. The algorithm starts by converting the spherical coordinates to cartesian coordinates so if that is what you have you can use only the two last rows. dx*radius is then the difference between the two points in the x direction and d*radius is the total distance between the points.

```
double sphericalDistance(double f1, double t1,
    double f2, double t2, double radius) {
    double dx = sin(t2)*cos(f2) - sin(t1)*cos(f1
        );
    double dy = sin(t2)*sin(f2) - sin(t1)*sin(f1
        );
    double dz = cos(t2) - cos(t1);
    double d = sqrt(dx*dx + dy*dy + dz*dz);
    return radius*2*asin(d/2);
}
```

    }
    return z;
}

```

Manacher.h
Description: For each position in a string, computes p[0][i] = half length of longest even palindrome around pos i, p[1][i] = longest odd (half rounded down).
Time: $\mathcal{O}(N)$

```

array<vi, 2> manacher(const string& s) {
    int n = sz(s);
    array<vi,2> p = {vi(n+1), vi(n)};
    rep(z,0,2) for (int i=0,l=0,r=0; i < n; i++)
        {
            int t = r-i+!z;
            if (i<r) p[z][i] = min(t, p[z][l+t]);
            int L = i-p[z][i], R = i+p[z][i]-!z;
            while (L>=1 && R+1<n && s[L-1] == s[R+1])
                p[z][i]++, L--, R++;
            if (R>r) l=L, r=R;
        }
    return p;
}

```

PalindromicTree.h
Description: Makes a trie of $\mathcal{O}(|S|)$ vertices containing all distinct palindromes of a string. Suffix links give the longest proper suffix/prefix of that palindrome which is also a palindrome.

Usage: S := 1-indexed string. append characters 1-by-1.
After adding the ith character, ptr points to the node containing the longest palindrome ending at i. Change ALPHA, ID() as problem requires.
Time: $\mathcal{O}(|S|)$

```

const int ALPHA = 26;
struct PalindromicTree {
    struct node {
        int to[ALPHA];
        int link, len;
        node(int a=0, int b=0) : link(a), len(b) {
            memset(to, 0, sizeof to);
        };
        V<node> T; int ptr;
        int ID(char x) { return x - 'a'; }
        void init() {
            T.clear(); ptr = 1;
            T.emplace_back(0, -1); // 0=Odd root
            T.emplace_back(0, 0); // 1=Even root
        }
        void append(int i, string &s) {
            while (s[i - T[ptr].len - 1] != s[i])
                ptr = T[ptr].link;

            int id = ID(s[i]);
            // if node already exists, return
            if (T[ptr].to[id]) return void(ptr = T[ptr
                ].to[id]);
            int tmp = T[ptr].link;
            while (s[i - T[tmp].len - 1] != s[i])
                tmp = T[tmp].link;

            int newlink = T[ptr].len == -1 ? 1 : T[tmp
                ].to[id];

            // ptr is the parent of this new node
            T.emplace_back(newlink, T[ptr].len + 2);

            // Now shift ptr to the newly created node
            T[ptr].to[id] = sz(T) - 1;
            ptr = sz(T) - 1;
        }
    };
};

```

MinRotation.h
Description: Finds the lexicographically smallest rotation of a string.
Usage: rotate(v.begin(), v.end());
v.begin()+minRotation(v), v.end();
Time: $\mathcal{O}(N)$

```

int minRotation(string s) {
    int a=0, N=sz(s); s += s;
    rep(b,0,N) rep(k,0,N) {
        if (a+k == b || s[a+k] < s[b+k]) {b += max
            (0, k-1); break;}

        if (s[a+k] > s[b+k]) {a = b; break; }
    }
    return a;
}

```

SuffixArray.h

Description: Builds suffix array for a string. sa[i] is the starting index of the suffix which is i'th in the sorted suffix array. The returned vector is of size n + 1, and sa[0] = n. lcp[i] = lcp(sa[i], sa[i-1]), lcp[0] = 0. The input string must not contain any nul chars.
Time: $\mathcal{O}(n \log n)$

```

struct SuffixArray {
    vi sa, lcp; // passing V<int> also works
    SuffixArray(string s, int lim=256) {
        s.push_back(0); int n = sz(s), k = 0, a,b;
        vi x(all(s)), y(n), ws(max(n, lim));
        sa = lcp = y, iota(all(sa), 0);
        for (int j = 0, p = 0; p < n; j = max(1, j
            * 2), lim = p) {

            rep(i,0,n) if(sa[i]>=j) y[p++] = sa[i]-j;
            fill(all(ws), 0);
            rep(i,0,n) ws[x[i]]++;
            rep(i,1,lim) ws[i] += ws[i - 1];
        }
        for(int i = n; i--;) sa[--ws[x[y[i]]]] = y[i];
        swap(x, y), p = 1, x[sa[0]] = 0;
        rep(i,1,n) a=sa[i-1], b=sa[i], x[b] =
            (y[a]==y[b] && y[a+j] == y[b+j]) ? p-1
                : p++;
    }
    for (int i=0,j; i<n-1; lcp[x[i++]] = k)
        for (k && k--, j = sa[x[i] - 1];
            s[i + k] == s[j + k]; k++);
} // loop with no body, wrong indentation
};

```

SuffixTree.h
Description: Ukkonen's algorithm for online suffix tree construction. Each node contains indices [l, r] into the string, and a list of child nodes. Suffixes are given by traversals of this tree, joining [l, r] substrings. The root is 0 (has l = -1, r = 0), non-existent children are -1. To get a complete tree, append a dummy symbol - otherwise it may contain an incomplete path (still useful for substring matching, though).
Time: $\mathcal{O}(26N)$

```

struct SuffixTree { // N ~ 2*maxlen+10
    enum { N = 200010, ALP = 26 };
    int toi(char c) { return c - 'a'; }
    string a; // v = cur node, q = cur position
    int t[N][ALP], l[N], r[N], p[N], s[N], v=0, q=0, m=2;

    void ukkadd(int i, int c) { suff:
        if (r[v]<=q) {
            if (t[v][c]==-1) { t[v][c]=m; l[m]=i;

```

10.3 Dynamic programming

KnuthDP.h
Description: When doing DP on intervals: $a[i][j] = \min_{i < k < j} (a[i][k] + a[k][j]) + f(i, j)$, where the (minimal) optimal k increases with both i and j , one can solve intervals in increasing order of length, and search $k = p[i][j]$ for $a[i][j]$ only between $p[i][j - 1]$ and $p[i + 1][j]$. This is known as Knuth DP. Sufficient criteria for this are if $f(b, c) \leq f(a, d)$ and $f(a, c) + f(b, d) \leq f(a, d) + f(b, c)$ for all $a \leq b \leq c \leq d$. Consider also: LineContainer (ch. Data structures), monotone queues, ternary search.
Time: $\mathcal{O}(N^2)$

DivideAndConquerDP.h
Description: Given $a[i] = \min_{l \leq i \leq k < h(i)} (f(i, k))$ where the (minimal) optimal k increases with i , computes $a[i]$ for $i = L..R - 1$.
Time: $\mathcal{O}((N + (h - l)) \log N)$
d38d2b, 18 lines

```
struct DP { // Modify at will:
    int lo(int ind) { return 0; }
    int hi(int ind) { return ind; }
    ll f(int ind, int k) { return dp[ind][k]; }
    void store(int ind, int k, ll v) { res[ind] = pii(k, v); }

    void rec(int L, int R, int LO, int HI) {
        if (L >= R) return;
        int mid = (L + R) >> 1;
        pair<ll, int> best(LLONG_MAX, LO);
        rep(k, max(LO, lo(mid)), min(HI, hi(mid)))
```

```
        best = min(best, make_pair(f(mid, k), k));
        store(mid, best.second, best.first);
        rec(L, mid, LO, best.second+1);
        rec(mid+1, R, best.second, HI);
    }
    void solve(int L, int R) { rec(L, R, INT_MIN, INT_MAX); }
};
```

10.4 Debugging tricks

- signal(SIGSEGV, [](int) { _Exit(0); }); converts segfaults into Wrong Answers. Similarly one can catch SIGABRT (assertion failures) and SIGFPE (zero divisions). _GLIBCXX_DEBUG failures generate SIGABRT (or SIGSEGV on gcc 5.4.0 apparently).
- feenableexcept(29); kills the program on NaNs (1), 0-divs (4), infinities (8) and denormals (16).

10.5 Optimization tricks
__builtin_ia32_ldmxcsr(40896); disables denormals (which make floats 20x slower near their minimum value).

10.5.1 Bit hacks

- x & -x is the least bit in x.
- for (int x = m; ; x = (x - 1) & m) // Here x is a submask of m if (!x) break;
- c = x&-x, r = x+c; Now ((r^x) >> 2)/c) | r is the next number after x with the same number of bits set.
- rep(b,0,K) rep(i,0,(1 << K)) if (i & 1 << b) D[i] += D[i^(1 << b)]; computes all sums of subsets, aka SOS DP.

variableBitset.h
bcf4b2, 8 lines

```
template<int N> void solve(int n) {
    if (n > N) {
        solve<min(2*N, 1'000'000)>(n);
        return;
    }
    // Now solving with bitset<N>;
}
// call solve<I>(n)
```

10.5.2 Pragmas

- #pragma GCC optimize ("Ofast") will make GCC auto-vectorize loops and optimizes floating points better.
- #pragma GCC target ("avx2") can double performance of vectorized code, but causes crashes on old machines.

- #pragma GCC optimize ("trapv") kills the program on integer overflows (but is really slow).

FastMod.h
Description: Compute $a \% b$ about 5 times faster than usual, where b is constant but not known at compile time. Returns a value congruent to $a \pmod b$ in the range $[0, 2b)$.
751a02, 8 lines

```
typedef unsigned long long ull;
struct FastMod {
    ull b, m;
    FastMod(ull b) : b(b), m(-1ULL / b) {}
    ull reduce(ull a) { // a % b + (0 or b)
        return a - (ull)((__uint128_t(m) * a) >> 64) * b;
    }
};
```

FastInput.h
Description: Read an integer from stdin. Usage requires your program to pipe in input from file.
Usage: ./a.out < input.txt
Time: About 5x as fast as cin/scanf.
7b3c70, 15 lines

```
inline char gc() { // like getchar()
    static char buf[1 << 16];
    static size_t bc, be;
    if (bc >= be) {
        buf[0] = 0, bc = 0;
        be = fread(buf, 1, sizeof(buf), stdin);
    } return buf[bc++]; // returns 0 on EOF
}
int readInt() {
    int a, c;
    while ((a = gc()) < 40);
    if (a == '-' ) return -readInt();
    while ((c = gc()) >= 48) a = a*10+c-480;
    return a - 48;
}
```

BumpAllocator.h
Description: When you need to dynamically allocate many objects and don't care about freeing them. "new X" otherwise has an overhead of something like 0.05us + 16 bytes per allocation.
745db2, 8 lines

```
// Either globally or in a single class:
static char buf[450 << 20];
void* operator new(size_t s) {
    static size_t i = sizeof buf;
    assert(s < i);
    return (void*)&buf[i -= s];
}
void operator delete(void*) {}
```

SmallPtr.h
Description: A 32-bit pointer that points into BumpAllocator memory.
2dd6c9, 10 lines

```
template<class T> struct ptr {
    unsigned ind;
    ptr(T* p = 0) : ind(p ? unsigned((char*)p - buf) : 0) {
        assert(ind < sizeof buf);
    }
    T& operator*() const { return *(T*)(buf + ind); }
```

```
T* operator->() const { return &***this; }
T& operator[](int a) const { return (&***this)[a]; }
explicit operator bool() const { return ind; }
};
```

BumpAllocatorSTL.h
Description: BumpAllocator for STL containers.
Usage: vector<vector<int, small<int>>>> ed(N);
bb66d4, 14 lines

```
char buf[450 << 20] alignas(16);
size_t buf_ind = sizeof buf;

template<class T> struct small {
    typedef T value_type;
    small() {}
    template<class U> small(const U&) {}
    T* allocate(size_t n) {
        buf_ind -= n * sizeof(T);
        buf_ind &= 0 - alignof(T);
        return (T*)(buf + buf_ind);
    }
    void deallocate(T*, size_t) {}
};
```

Unrolling.h
5e0f99, 14 lines

```
#define F {...; ++i;}
int i = from;
while (i&3 && i < to) F // for alignment, if needed
while (i + 4 <= to) { F F F F }
while (i < to) F

int n32 = n / 32;
while (n32--) {
#define F(i) a[i] = a[i] == x ? y : a[i];
#define FP(i) F(i+0) F(i+1) F(i+2) F(i+3)
    FP(0); FP(4); FP(8); FP(12);
    FP(16); FP(20); FP(24); FP(28);
    a += 32;
}
```

Dates.h
Description: Convert dates to day number and reverse.
b203cf, 18 lines

```
int date_to_int(int y, int m, int d) {
    if (m <= 2) y--, m += 12;
    return 365*y + y/4 - y/100 + y/400 + (153*m - 457)/5 + d - 306;
}

void int_to_date(int z, int &y, int &m, int &d) {
    z += 306;
    int a = z + 68569;
    int b = 4*a/146097;
    a = a - (146097*b + 3)/4;
    int c = 4000*(a + 1)/1461001;
    a = a - 1461*c/4 + 31;
    int e = 80*a/2447;
    d = a - 2447*e/80;
    a = e/11;
    m = e + 2 - 12*a;
    y = 100*(b - 49) + c + a;
}
```

Techniques (11)

techniques.txt 33 lines

Invariants, Monovariants, whatever-variants, see what changes and what does not from start to finish.

Greedy: sorting, matroid, matroid intersection , add and remove, etc.

Extreme values for greedy: Find the maximum achievable. Is it always achievable?

Figure out the necessary conditions. Maybe they are also sufficient (and vice versa)

Fix a parameter and maximize the result wrt that parameter. Can you binary search there too?

Construct the lower/upper bounds.

Guess the form, and use induction to prove it.

When asked about how many beautiful things exist, you must ask how it is beautiful.

Backward solving.

Look at the constraints properly.

Thoroughly read the problem again.

Do your integers fit in int? Convert to long long when dealing with large bitshifts and what not. Check constants and single letter variables.

Try out cases, bruteforce for patterns if pc is available. If many people solved it, it is usually something simple. But dont get stuck in trying to find patterns.

Try to simplify the problem, or solve simpler cases: functional graphs, DAGs, cycles, and strongly connected components instead of directed graphs; trees, cycles, and biconnected components instead of graphs; paths instead of trees; 1D instead of 2D; permutation instead of arrays; etc.

Pigeonhole principle, birthday paradox, inclusion-exclusion, double counting, etc.

Maybe your idea is fast enough in practice or maybe your complexity analysis is too loose.

BFS, DFS, BFS trees, DFS trees, hall-marriage for bipartite graphs.

Topological sorting can maybe make dp on DAGs faster or save memory.

Min cut is powerful for stuff like the project selection problem: n machines with cost q_i and m projects with revenue p_i , with each project requiring a set of machines.

SQRT decomp for time or memory, binary jumping , and other forms of divide and conquer.

Online MO?

Two-pointer

Offline preprocessing

Bitsets to optimize silly bruteforce

Games: nim, Grundy, pattern, etc.

Geometry: isometries and other transformations (manhattan-to-chebyshev, translations, rotations, etc), line sweep, radial sweep, lots of sweeping. Turn other problems into geometry problems.

Hashing: strings, sets, multisets, rooted trees, ordered rooted trees, etc. Super powerful.

String: tries, suffix trees, suffix arrays, kmp, etc.

Randomization.

HLD, centroid decomp, treaps, seg tree, persistent seg tree, sliding window, etc.

FFT and friends: generating functions.

DP: memory optimization, CHT, LiChao, D&C, Knuth, functions as values, aliens trick (for problems involving partition into k segments, set a penalty for creating partitions, then binary search on penalty value and compare with the optimal solution where any number of partitioning is allowed), prefix sum, seg tree, etc.

Remember about boundary cases.

Functional graphs, especially for permutation problems.

Bitwise or randomized for interactive problems with logarithmic number of allowed inputs .
